Open Access

A comparative study of *in silico* prediction of pK_a

C Matijssen

From 5th German Conference on Cheminformatics: 23. CIC-Workshop
Goslar, Germany. 8-10 November 2009

The ionization constant (pK_a) is the measure of the strength of an acid or base in a solution. Most ligands act as a weak acid or base. Accurate determination of pK_a is important as it can improve the pharmaceutical properties of a compound [1]. In general, charged compounds have better solubility, but are less effective in membrane permeation. Therefore, optimization of the pharmacokinetic profile of a compound can be performed by increasing or decreasing its ionization by changing functional groups. Another role for optimization of the charged group could be the interaction with its target. Changing the charge on the functional group could improve the interaction with its associated target and result in improved binding affinity.

Different methods have been developed for the computational determination of pK_a values. These can be based on different methods such as QSAR [2] or quantum chemistry approaches [3]. These two methods differ considerable in terms of computational resource and hence, the time needed for a prediction. Depending on the number of ligands that needed prediction and time available, a choice for one method can be made.

A comparison between several pK_a predictors (Pipeline Pilot, Moka, Epik and Jaguar) was made. All methods perform well when a diverse set of ligands which covers a range of pK_a values is considered. However, when optimizing a series of compounds the influence of small changes to the molecule and its effect on pK_a becomes more difficult to predict.
